The host side needs to set the waiting time, timeout time, number of retries. Incorrect settings may cause abnormalities such as read errors and slow write responses. In order to obtain good communication quality, please refer to the following examples to set

Item	Name	Setting value	unit
1	Wait time	50	ms
	Response delay time		
	Delay time		
2	Timeout	1000	ms
3	Retry number	1	---

#### Function Code

Function Code	Command	Content
'R' (52H)	Read	Reading 1 register value from slave controller.
'M' (4DH)	Modify	Temporarily write 1 register value to controller's RAM. (When reboot the data will be lost)
'W' (57H)	Write	Write 1 register value to controller's RAM and EEPROM. (Data are maintained after power off)

#### Checksum

Add all the values from "Command" to the end of "Data". The result is Checksum (1 byte).

step 1 : CRC = FFFF(Hex) 2 Byte

step 2 : Calculate XOR with 1st data (start with n=1) and the low byte of CRC.

step 3 : If CRC data byte is 1

→ CRC = CRC >> 1;

CRC<sup>^</sup> = 0XA001;

or

→ CRC = CRC >> 1;

step 4 : Repeat step 3, do 8 times.

step 5 : Repeat step 2~4 finished the end of one.

## 6.6 EEPROM Protection Function

The memory system of the FE series controller is composed of EEPROM, and the number of times and years of memory of the EEPROM has its physical limitations, so a 24C16 EEPROM can be written to about 1 million times. The data retention is about 10 years. If the Master always send write command in high-speed communication, then the EEPROM has a high probability of being over-cycle in a short time, which means that the memory cell failure, the data can't be storage. To prevent this error, the FE series controller provides two protection modes, active protection and passive protection, please refer to the following description.

### (1) Active Protection

The controller will automatically compare the data to be written, whether it is in Modbus RTU or TAIE protocol, when the received data is the same as the last received data, the controller will not write to EEPROM. The controller will only write to the EEPROM when it is different from the last received data.

EX : SV initial value =0, Master continue write to controller's SV

1. Master send SV =1000  
FE EEPROM : will write to 1000
2. Master send SV =1000  
FE EEPROM : No action
3. Master send SV =1000  
FE EEPROM : No action
4. Master send SV =500  
FE EEPROM : will write to 500
5. Master send SV =500  
FE EEPROM : No action
6. Master send SV =500  
FE EEPROM : No action

### (2) Passive Protection

Set the parameter W\_MD to OFF, when the controller receives the write command, it will only write data to the CPU RAM without writing data to the EEPROM. The advantage of this method is that you don't have to worry about write cycles of EEPROM, and the disadvantage is that the previously written data will not be storage after reboot.

EX1 : Set W\_MD =OFF, SV initial =0, Master send SV =1000

Master send : 01H 06H 00H 01H 03H E8H D8H B4H  
FE RAM (SV) =1000  
FE EEPROM : No action

EX2 : Set W\_MD =ON, SV initial =0, Master send SV =1000

Master send : 01H 06H 00H 01H 03H E8H D8H B4H  
FE RAM (SV) =1000  
FE EEPROM : write to 1000

- ※ This parameter (W\_MD) can't be modify via communication, only available modify by the controller keypad.
